# Enhancing a Ranking System: Practical Applications to Information Retrieval Systems and BCS Rankings 

Kee-cheol Lee<br>Computer Engineering Department, Hongik University, Seoul, Korea 121-791

#### Abstract

The rankings of the members fora given domain, if provided, can be thought to be the efficient description of the domain and help us make decisions accordingly. For example, each web search engine like Google retrieves queryrelevant documents and shows us highly ranked ones in ascending order of their ranks. However, if we have two or more rankers or ranking systems with their own expertise for one domain, we may be puzzled what to choose or how to fix their differences. In this paper, the issue of how to combine two experts' rankings is treated. We suggest some methods of combining two different rankings. For practical applications, two domains were selected to test and validate our method. First, two different rankings generated by changing some portion of our information retrieval system were selected and our experiments show that the resulting average rank of top ten relevant documents, for example, was considerably improved. The second domain we tried may be thought to be almost improbable. The question is if American college BCS football ranking, officially published from the middle of the football season, can be modified to better predict the four week later BCS ranking itself. Our experiments show that some computer-based ranker help enhance the predictability of the future BCS ranking.

Keywords: ranking, machine learning, information retrieval, search engines, TF-IDF, NCAA football, computer rankings, BCS ranking

## I. INTRODUCTION

Ranking is a simplified decision-making method of a given system such that it makes its users easily understand the current situation and behave accordingly. Rankrelated research has been conducted in bio-informatics areas, where rank normalization has been applied to replace each observation by its fractional rank(the one divided by the total number of genes) within array[1][2]. With this rank normalization robustness to non-additive noise is achieved at the expense of losing some parametric information of expressions[3]. In information retrieval areas, rank normalization like rank shifting and rank freezing has been studied for relevance feedback of search engines[4], which must show us a small number of highly ranked relevant web pages in the order of relevance, despite the enormous amount of web pages relevant to given queries. The problem is that we may have two or more rankers that decide ranking in different ways, and each of which may have its own expertise. Given two or more experts' opinions of the rankings for the same domain, the question arises if and how a different ranking should be referenced. Recently in economics area, the issue of simultaneous consultation and utilizing two informed experts' opinions for decision making has been studied[5][6][7], but we believe that this issue should be processed mathematically without any human bias to be usable in broader problems like search engines and sports ranking predictions. To reference and utilize another expert's ranking, a combining function should be defined and tested to convert original rankings. If we have an enough past ranking sequence, the appropriate combining functions may be applied such that they better predict
future unknown rankings. Suspecting that just averaging two rankings may lose the expertise of each expert ranker, we decided to give another ranker a supporting status to improve the main system ranker. We suggest some combining functions and conditions upon which those functions may be applied, and applied our method to two quite different areas, i.e., re-ranking relevant documents retrieved by search engines, and improving the BCS rankings, the prestigious official American college football rankings, in terms of predicting future BCS rankings better website.

## II. COMBINING RANKINS

Just averaging two rankings may possibly blur the expertise hidden in each published ranking system. Therefore to keep the original expertise, combining functions should be used appropriately. We suggest the following basic method.

Let setl be the set of elements ranked by rankerl, main ranker;

Let set2 be the set of elements ranked by ranker2, auxiliary ranker;

Let default_rankl(i) be the rank assignable to any element $i$ not belonging to setl;

Let $\operatorname{rankl}(i)$ be the rankerl's rank of element $i$ and rank2(i) be the ranker2's rank of element $i$;
for each $i \in(\operatorname{set} 1 \cup \operatorname{set} 2)$
\{
if (i\#setl)
rankl(i) = default_rankl(i);
if (i¥set2)

$$
t m p \_r a n k l(i)=\operatorname{rankl}(i)
$$

else

$$
\begin{aligned}
& \text { tmp_rankl }(i)=\text { CombineRanks(rankl(i), } \operatorname{rank2(i));} \\
& \text { \} // end of for }
\end{aligned}
$$

Sort and re-rank all elements in (set1Uset2) in ascending order of ( tmp_rankl(i), rankl(i) );
Let new_rankl(i) be the modified new rank of an element $i$, after the above steps; Here, default_rankl(i) is the rank to be assigned to any element not belonging to setl, and its value should be (pessimistically) big enough not to overaffect final rankings. For example, in case of top 25 ranking only predictions, a value much larger than 25 , e.g. 35 , was used for the experiment. If unranked ones were considered as $26^{\text {th }}$ as in many prediction systems, it could over-affect final rankings. The final sorting is done first by tmp_rankl(i), and rankl(i) is used as a tie-breaker. The combining function Combine Ranks(r1, r2) can be regarded to be a kind of an averaging function, and some of the potential candidate functions which may be used are listed below.
// arithmetic mean
doubleAri(double $r 1$, double $r 2$ )
$\{$ return $(r l+r 2) / 2.0$; $\}$
$/ /$ average of squared arithmetic mean
doubleAri2(double $r 1$, double $r 2$ )
\{ returnsqrt(( $r 1 * r 1+r 2 * r 2) / 2.0) ;$ \}
// harmonic mean
double $\operatorname{Har}$ (double $r 1$, double $r 2$ )
\{ return 2.0/(1.0/rl + 1.0/r2); \}
// average of squared harmonic mean
doubleHar2(double $r 1$, double $r 2$ )
\{ returnsqrt(2.0/(1.0/(r1*r1)+1.0//(r2*r2)); \}
Har function can be thought to consider the ranks of the ranker 2 more than Ari function, and Ari2 and Har2 are the second order version of Ari and Har. Therefore, the return values of the four combining methods are in the order of Har2, Har, Ari, and Ari2. The return values of the above mentioned combining functions are summarized in TABLE I(a) for some example data set. TABLE I(b) and (c) show the corresponding results of the temporary ranks and the final ranks for the same data set.

TABLE I
RANK COMBINING EXAMPLE
(a) Combined ranks, if applicable

| rank1 | rank2 | CombineRanks |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Ari | Ari2 | Har | Har2 |
| 1 | 2 | NA | NA | NA | NA |
| 2 | 1 | 1.5 | 1.58 | 1.33 | 1.26 |
| 3 | 7 | NA | NA | NA | NA |
| 4 | 6 | NA | NA | NA | NA |

| 5 | 5 | NA | NA | NA | NA |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 6 | 4 | 5 | 5.10 | 4.8 | 4.71 |
| 7 | 3 | 5 | 5.39 | 4.2 | 3.90 |
| 8 | 10 | NA | NA | NA | NA |

| 10 | 8 | 10 | 10 | 9 | 9 |

III. EHANCING SEARCH ENGINE RANKINGS

We have constructed some search engine system to be used for information retrieval-related class assignments [8][9][10]. Its rankings are based on TF-IDF method, where by TF we mean some measure of a term frequency for a document, and by IDF(inverse document frequency) we mean a measure of a word in the collection, including entropy or noise measure. We are not going to delve into the details of our information retrieval system[11]. For this experiment, TF variations like the following TF1 and TF2 were used.

$$
\begin{align*}
& T F 1_{i j}=\log _{2}\left(\text { freq }_{i j}+1\right) / \log _{2} t_{j}  \tag{1}\\
& T F 2_{i j}=t t_{i j}  \tag{2}\\
& t f_{i j}=\text { freq }_{i j} / \text { maxfreq }_{j}
\end{align*}
$$

freq $_{i j}=$ frequency of term $i$ in document $j$ maxfreq $_{j}=$ max.frequency of any term in document $j$ $t_{j}=$ the number of unique terms in document $j$

Table II summarizes CACM test collection used for this experiment. It contains 3,204 documents and 52 queries.
The experimental results for two rankers which utilize TF1 and TF2 are shown in the $2^{\text {nd }}$ and $3^{\text {rd }}$ column of TABLE III TF1, suggested by Harman[12], turned out to be better than TF2, a simple relative term frequency, in terms of all seen relevant documents and top 10 documents. The question is if and how the search engine performance based on TF1 can be improved by referencing an inferior ranker(TF2-based ranker). The last two columns of TABLE III show us that by combining the ranks of the ranker2 to those of the ranker1 by the arithmetic averaging function(Ari) and the harmonic averaging function(Har) defined before, more than $5 \%$ of improvement has been obtained. This means that referencing and methodically utilizing the ranks of the ranker2, even if they are not overall satisfactory, could possibly improve the ranking quality of the rankerl.

TABLE II
INFORMATIONRETRIEVAL TEST COLLECTION AND GENERAL RESULT SUMMARY (3204 CACMDOCUMENTS, 52 QUERIES)

|  | avg. $\pm \sigma$ | median | $\min$ | $\max$ |
| :---: | :---: | :---: | :---: | :---: |
| terms/doc. | $63.0 \pm 51.5$ | 38 | 13 | 356 |
| uniq.terms/doc. | $44.7 \pm 32.0$ | 29 | 10 | 241 |
| terms/query | $19.9 \pm 14.7$ | 14 | 2 | 68 |
| uniq.terms/query | $16.4 \pm 11.1$ | 12 | 2 | 45 |
| rel.docs/query | $11.9 \pm 8.7$ | 10 | 1 | 38 |
| recall | $0.84 \pm 0.19$ | 0.89 | 0.35 | 1.0 |
| returned docs | $524.2 \pm 271.3$ | 454.5 | 21 | 1109 |

TABLE III

## IV. IMPROVING NCAA FOOTBALL BCS RANKINGS

The next domain for our experiments is the BCS which is considered to be the most prestigious ranking system for evaluating American college football teams. In 2013 season, for example, BCS rankings were officially published for eight weeks from week 8 to week 15 after the football season began. The BCS ranking is generated based on many factors, which are outside of the scope of this paper. The question here is if we can enhance the current week BCS ranking. One of the difficulties of this
domain is that no real ranking exists, so we decided to use the predictability of the future (four week later) BCS ranking to determine the validity of our modified BCS ranking. BCS and other rankings are available online[13][14][15], and we summarized BCS ranking together with 6 computer-based rankings and computeraveraged ranking for $8^{\text {th }}$ to $15^{\text {th }}$ football season weeks of the year 2013. TABLE IV is a sample ranking data for $8^{\text {th }}$ football week. The max rank provided for BCS week 8 ranking is 42 , but we have just top 25 of 6 computer rankings, and top 27 of the computer average ranking.

TABLE IV
BCS AND COMPUTER NCAAFOOTBALL RANKINGS FOR WEEK 8, 2013

| wk8 (Oct. 20, 2013) |  |  |  |  |  |  |  |  |

| Tennessee | 39 |  |  |  |  |  |  |  |
| Pittsburgh | 42 |  |  | 24 |  |  |  |  |

TABLE $V$ shows us the predictability of 4 week later BCS ranking in terms of average rank errors. As expected, any week $n$ computer-based rank predicts week $n+4$ BCS ranking better than week $n \mathrm{BCS}$ ranking.

The reason might be that each system has a different kind of expertise and that for computer rankings just top 25 are used for prediction, and the rest universities not ranked were assigned very pessimistic $\operatorname{rank}(i . e .35)$ for experiments.

The fact that the 4 week later BCS predictability of computer average ranking is comparatively better than those of other computer rankings just reflects that the average computer ranking itself is actually one important factor in deciding the BCS ranking.

TABLE V
Four Week Later BCSRanking Prediction Performance of the Current BCS and Various Computer Rankings (Original PERFERMANCE):AVERAGE RANK ERROR

| ranker1(*) | BCS | AH | CM | JS | KM | PW | RB | CAvg |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $* \mathbf{8} \rightarrow$ BCS12 | 5.84 | 6.8 | 7.08 | 7.92 | 7.92 | 6.32 | 8.92 | 6.44 |
| $* 9 \rightarrow$ BCS13 | 5.76 | 7.12 | 7.68 | 7.04 | 7.56 | 6.72 | 8.44 | 6.64 |
| $* \mathbf{1 0} \rightarrow$ BCS14 | 5 | 5.6 | 6.04 | 5.96 | 5.76 | 6.04 | 6.4 | 4.76 |
| $* \mathbf{1 1 \rightarrow} \rightarrow$ BCS15 | 4.2 | 4.84 | 5.56 | 5.92 | 6.12 | 5.88 | 4.76 | 5.32 |
| dev. avg. | 5.20 | 6.09 | 6.59 | 6.71 | 6.84 | 6.24 | 7.13 | 5.79 |
| dev. $\sigma$ | 0.66 | 0.92 | 0.84 | 0.83 | 0.92 | 0.32 | 1.66 | 0.78 |
| enh.\% | 0 | -17.1 | -26.7 | -29.0 | -31.5 | -20.0 | -37.1 | -11.3 |

TABLE VI summarizes the 4 week predictability of the modified BCS ranking in terms of rank errors by utilizing each computer ranker as an auxiliary expert to modify the current week BCS ranking. This experiment has been conducted for the data for eight weeks (i.e., week 8 to week 15) of the 2013 football season. Surprisingly,

TABLE VI
FOUR WEEK LATER BCSRANKING PREDICTION PERFORMANCE OF THE CURRENT BCSRANKING MODIFIED BY REFERENCING COMPUTER RANKINGS USING ARICOMBINING FUNCTION:AVERAGE RANK ERROR

| B ranker1 | BCS |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| C ranker2 | - | AH | CM | JS | KM | PW | RB | CAvg |
| S Comb. fcn. | - | Ari | Ari | Ari | Ari | Ari | Ari | Ari |
| $\begin{gathered} \mathrm{BCS}^{\prime} 8 \rightarrow \mathrm{BC} \\ \mathrm{~S} 12 \end{gathered}$ | 5.84 | 5.88 | 5.72 | 5.88 | 5.84 | 5.72 | 6.16 | 5.88 |
| $\begin{gathered} \text { BCS' }^{\prime} \rightarrow \mathrm{BC} \\ \text { S13 } \end{gathered}$ | 5.76 | 5.8 | 5.64 | 5.88 | 5.6 | 5.8 | 5.88 | 5.88 |
| $\begin{aligned} & \text { BCS' } 10 \rightarrow \mathrm{~B} \\ & \quad \text { CS } 14 \end{aligned}$ | 5 | 5.08 | 5 | 5.12 | 4.92 | 4.96 | 5.16 | 4.92 |
| $\begin{gathered} \text { BCS' } 11 \rightarrow \mathrm{~B} \\ \text { CS15 } \end{gathered}$ | 4.2 | 4.2 | 4.12 | 4.4 | 4.04 | 4.16 | 4.28 | 4.2 |
| dev. avg. | 5.20 | 5.24 | 5.12 | 5.32 | 5.10 | 5.16 | 5.37 | 5.22 |
| dev. $\sigma$ | 0.66 | 0.68 | 0.64 | 0.62 | 0.70 | 0.66 | 0.73 | 0.71 |
| enh.\% | 0 | $\begin{gathered} - \\ 0.77 \end{gathered}$ | 1.54 | $2.31$ | 1.92 | 0.77 | $3.27$ | -0.38 |

utilizing CM and KM computer rankers improves the predictability by $1.54 \%$ and $1.92 \%$, respectively. This improvement is amazing because it is hard to assume that any other ranking than current BCS can better predict 4 week later BCS ranking itself, considering that the method of calculating current BCS remains the same as that of calculating other week BCS. The rationale is that if we modify the current BCS ranking closer to the true ranking, it may be eventually reflected in the future. BCS utilizes the average of all computer rankings as a factor in deciding its ranking, but our method may suggest how and which computer ranking should be considered for ranking better.

## V. CONCLUSION

If the member rankings are provided for a given domain, they can be efficiently used for their users' decision making processes. However, when we are given different rankings for the same domain, and if each of the ranking producing systems or experts has its own expertise, we are puzzled how to react. In this paper, we suggest a general paradigm for combining conflicting rankings. For that purpose, ranking combining functions were suggested, and two domains were selected for testing and validating our method. First, the issue of handling two different rankings produced by selecting different term-frequency definitions was treated. The test results for that domain is very encouraging, especially in terms of the average rank of top ten relevant documents for given queries. The second domain we chose is the BCS ranking for the American college football. By utilizing computer-based ranking systems, we experimented to seethe possibility of enhancing the predictability of the current BCS ranking. We found some computer ranking may help enhance BCS ranking in terms of predicting four week later BCS ranking itself, which is a very encouraging result.
